3D Atmospheric Structure

- Atmospheric structure is largely defined by the distribution of temperature, humidity, and winds.
- Winds govern the transport of energy in the atmosphere and represent a fundamental component of the Earth system
- National academy of science named 3D atmospheric winds as key targeted observable in the decadal survey for quantifying movement of water vapor, pollutants/aerosols, cloud dynamics, and large scale circulation.
- Applications include: Numerical weather prediction, data assimilation, wildfire plumes, ocean currents/winds, mesoscale convection, and more.

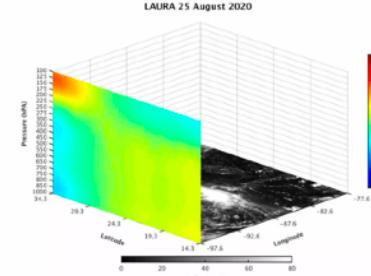

Observing the atmosphere

Lidar winds

Radiosonde

Sounders

Scatterometer

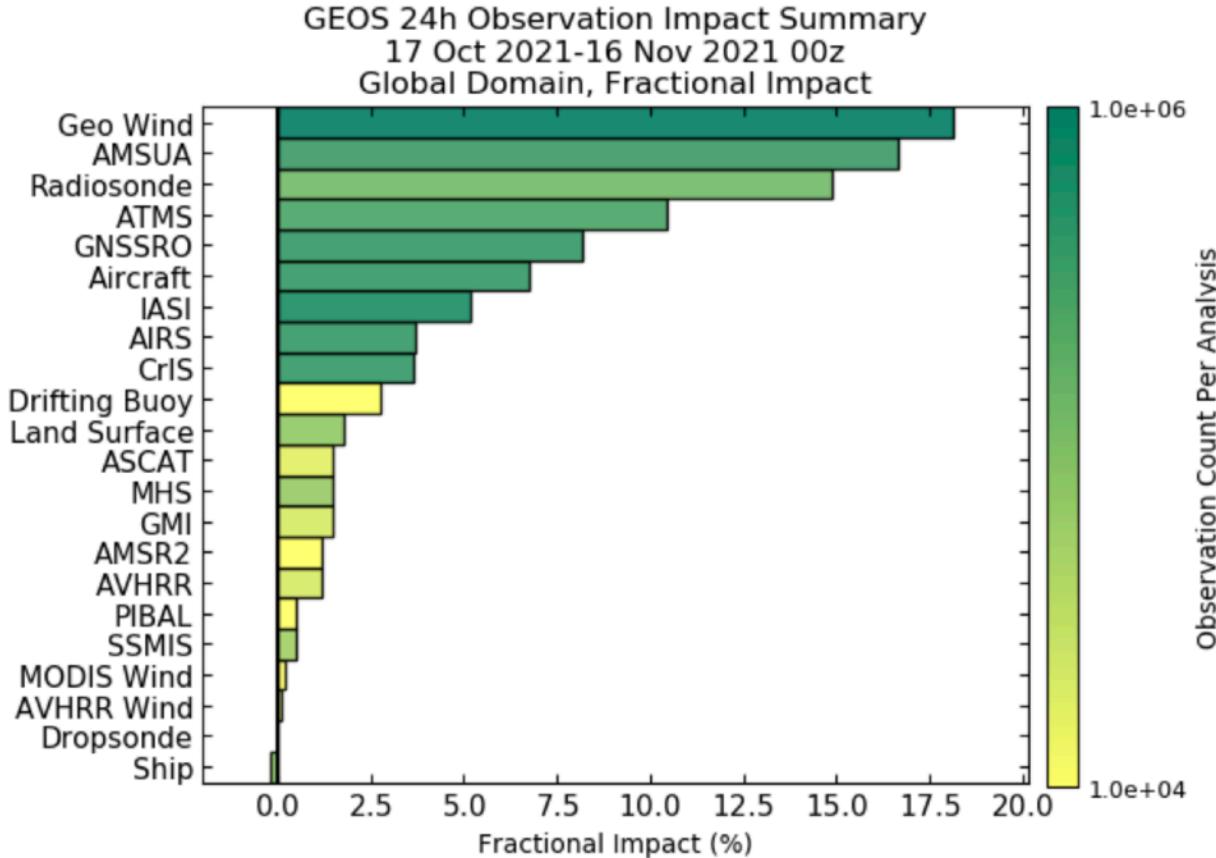

Weather stations

Radar

- Rawinsondes and stations = ground truth observations.
- Activate sensors include Lidar, scatterometers, and radar
- Low earth orbit satellites have infrequent revisit times not well suited for global monitoring
- Observations are assimilated in numerical weather forecasts as initial conditions

Observations for data assimilation

- Atmospheric Motion Vectors (AMVs) from geostationary have the highest impact per observation.
- Radiosondes and Sounder observations also have high impact.
- Dense and higher resolution data could have a large impact in NWP.

Geostationary satellites

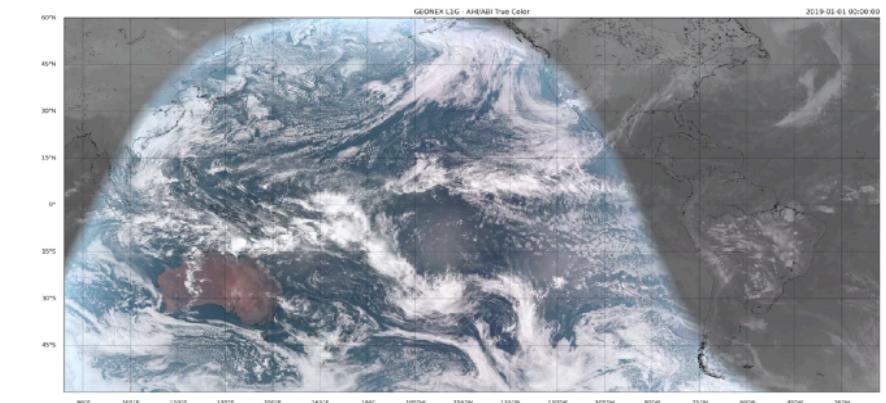

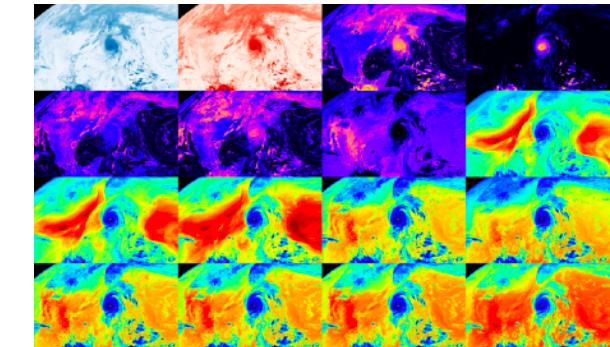

Specifications

- GEO Imaging sensors produce high-frequency multi-spectral data
 - GOES-16/17/18, Himawari-8/9, GeoKompSat-2a, FY-4
- Spatial: 0.5-2 km resolution
- Temporal: 1-10 minutes
- 5-16 spectral bands
- Global coverage from multiple satellites

Some Applications

- Atmospheric motion vectors (Velden 1997; Apke 2022; Carr 2019)
- Quantitative precipitation estimation (Sadeghi 2019)
- Land surface temperature (Duffy 2022)
- Convective storm patterns, anvil plumes (Bedka 2021)
- Air quality (Kondragunta 2020)
- Vegetation (Hashimoto 2021)
- Wildfire detection (Xu 2017)
-

16 Visible and Infrared bands

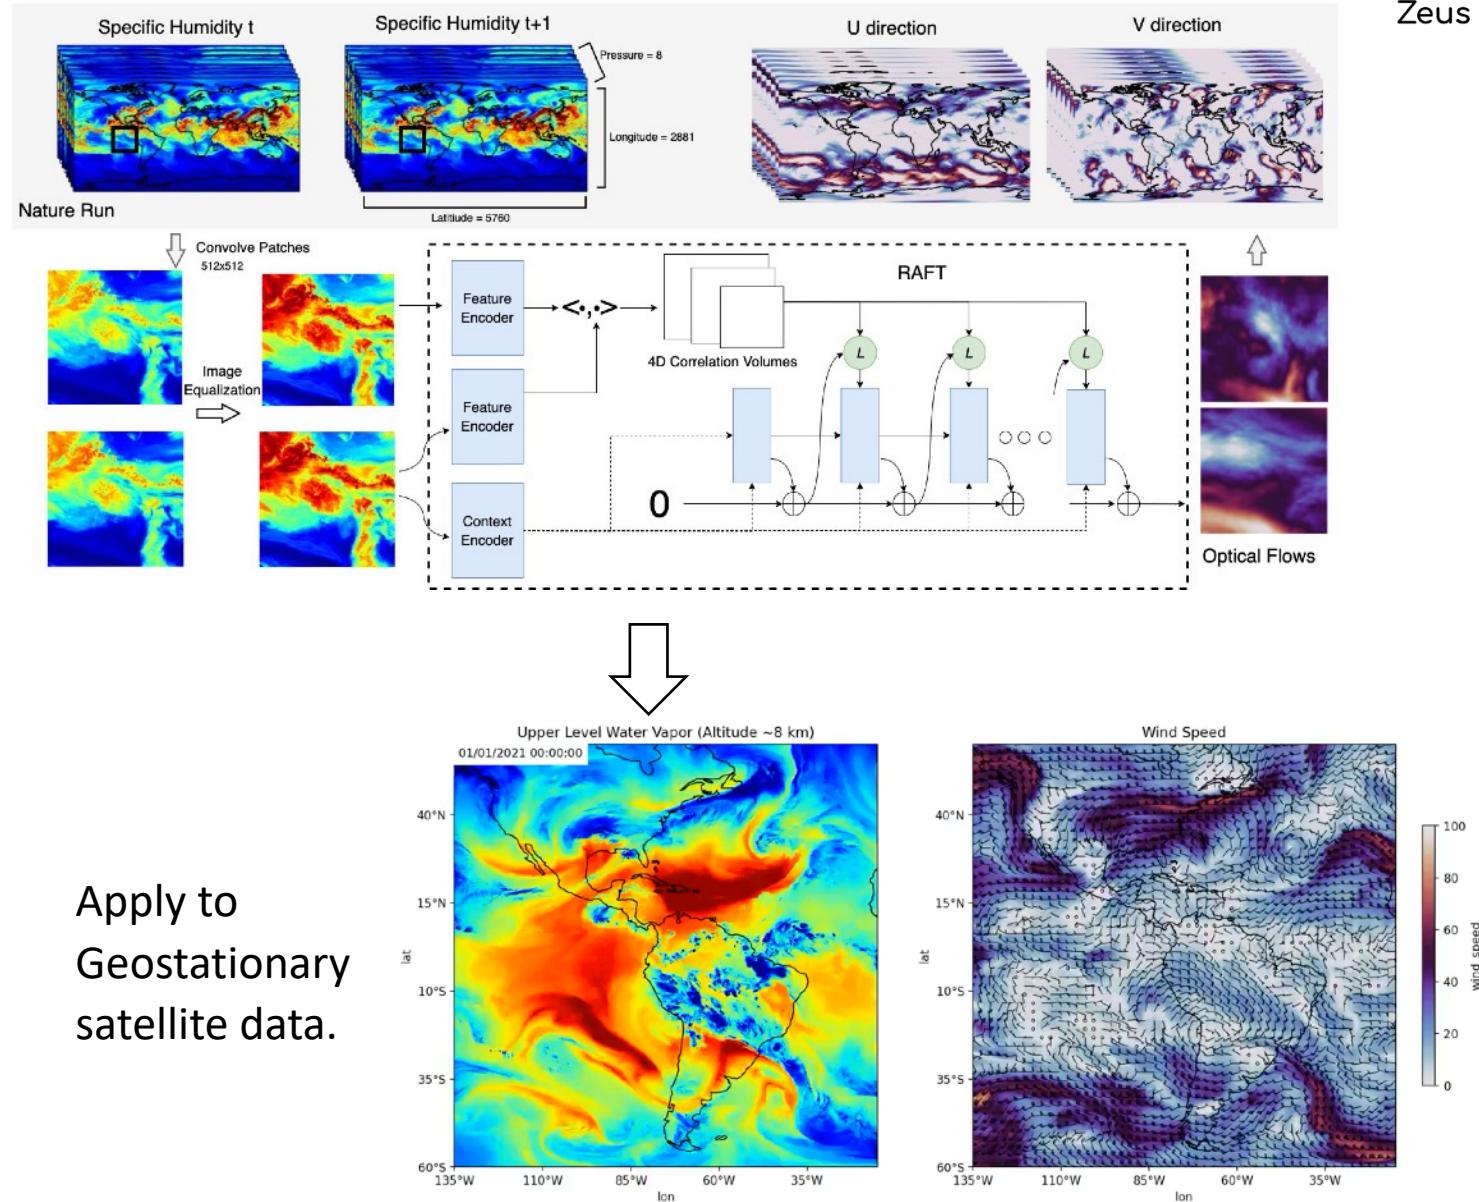

GeoNEX L1G dataset - Near global, 10 minute, 2km

WindFlow

- ML for Atmospheric Motion Vectors (AMVs)
- Extract horizontal motion from sequences of humidity.
- Learn from Numerical weather simulations which are widely available as *synthetic* data. Apply to GEO.
- Flexible choice of optical flow architectures. Results compare four networks where we found RAFT to be the best performing.

$$Loss = ||Y - F(I_0, I_1)||_1$$

GEOS-5 Nature Run: Flows across dimensions and scales

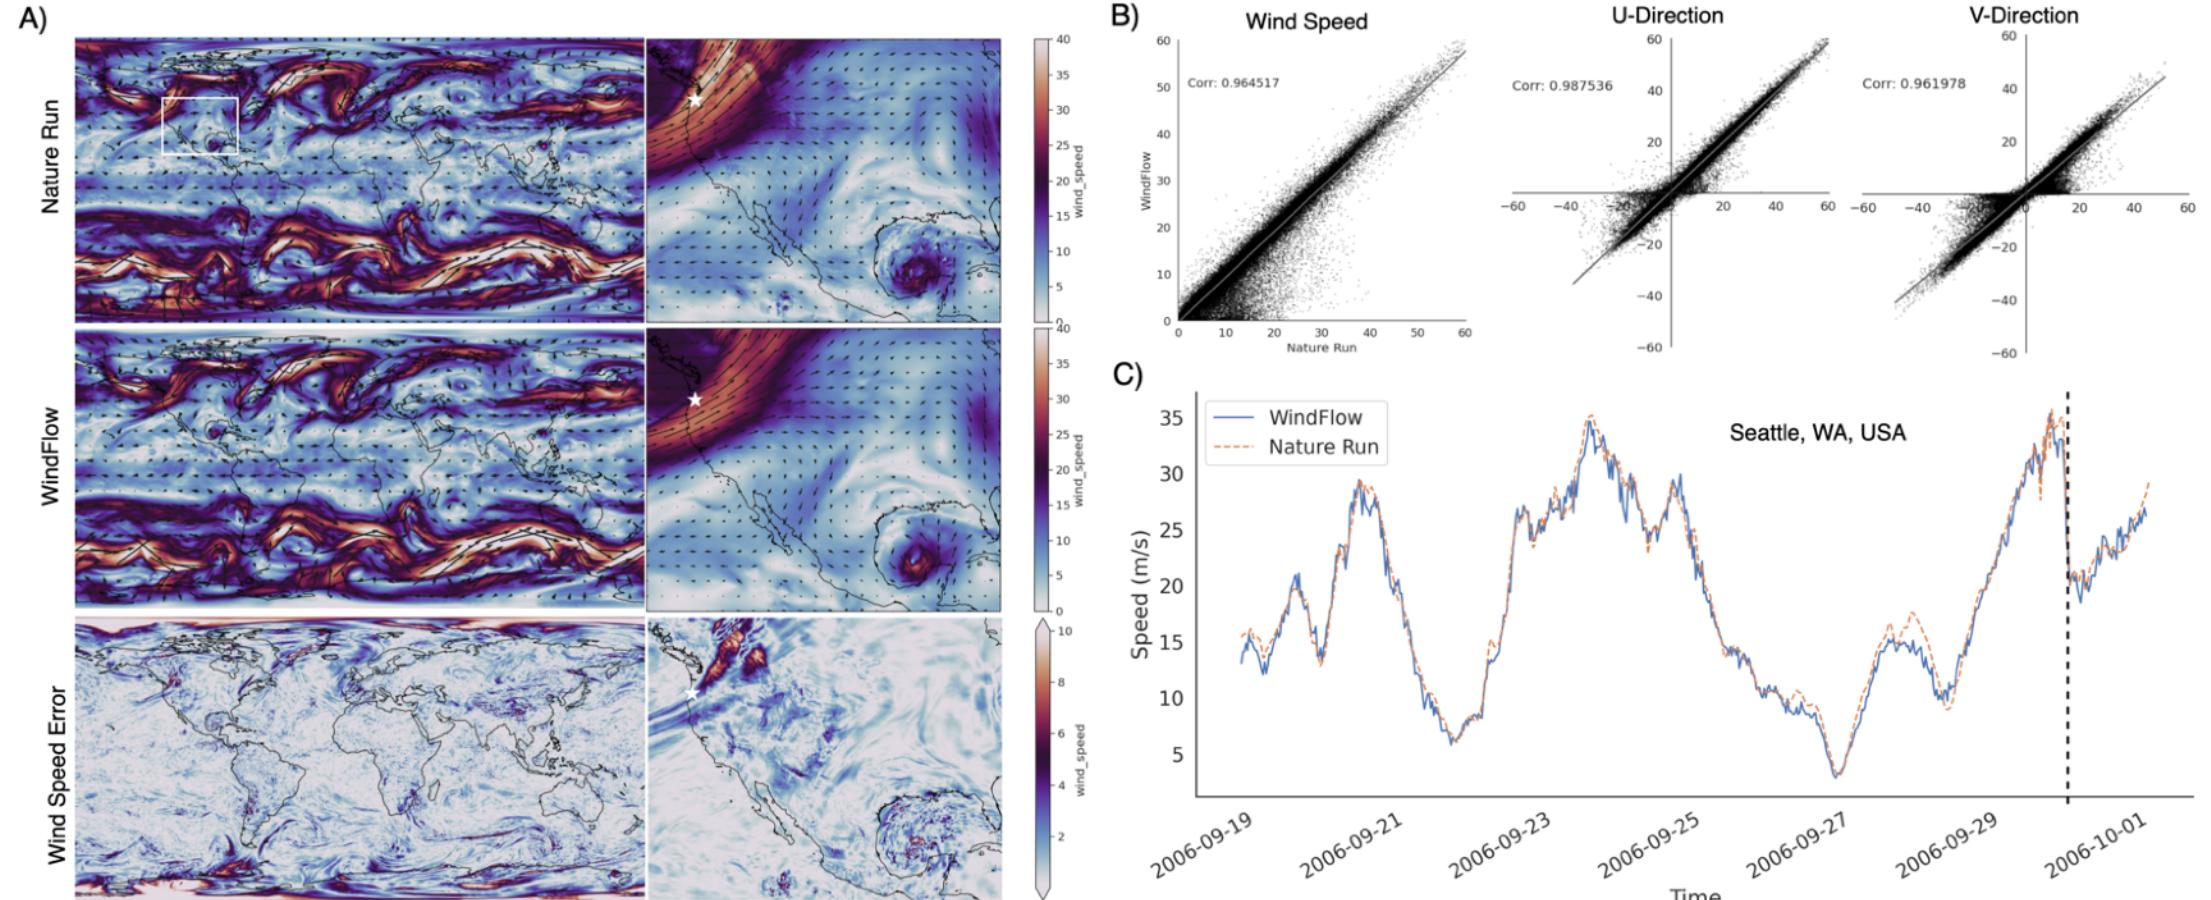

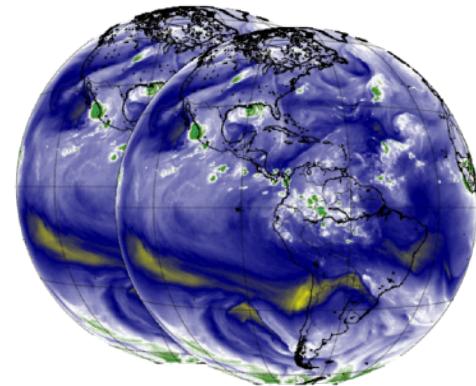

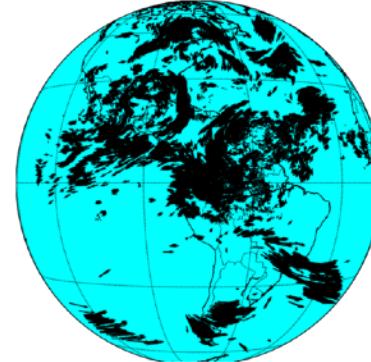

Figure: Results on nature run test set. A) Global and mesoscale comparison, B) U, V, and wind speed scatter plots, C) Time-series

Satellite based winds - Rawinsonde Comparison

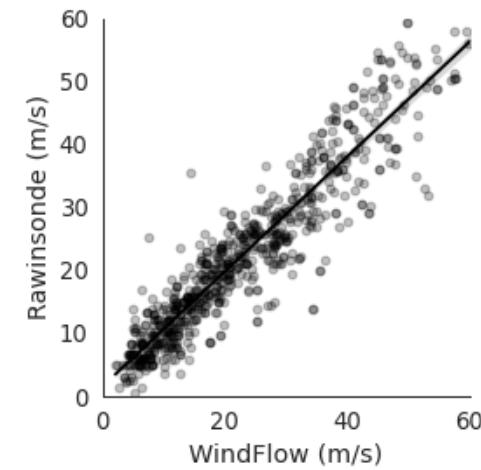

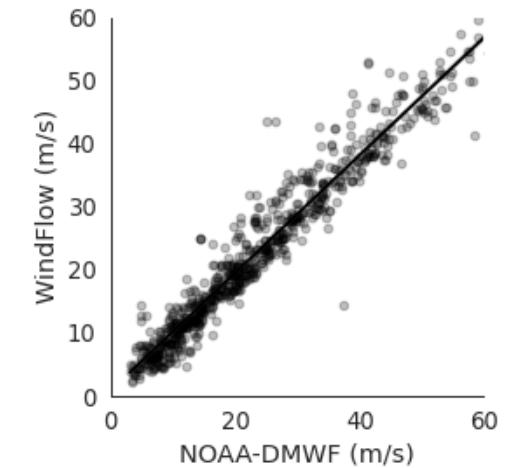

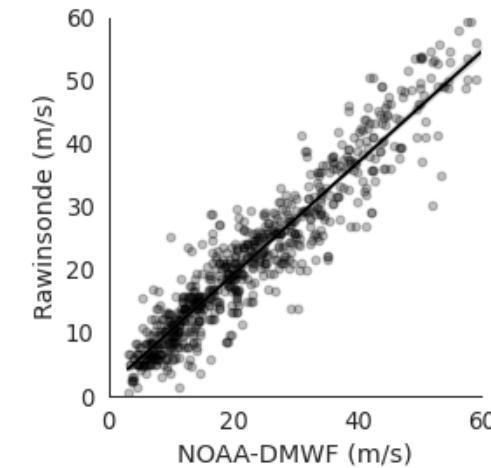

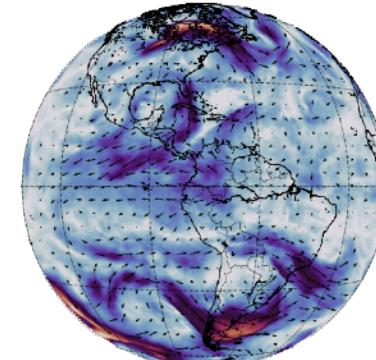

Input: Pair of GOES-16
Band 8 Infrared Water
Vapor

Motion Winds

NEX-AI WindFlow

Combine models for 3D Structure

Can we reconstruct vertical profiles from GEO imagery?

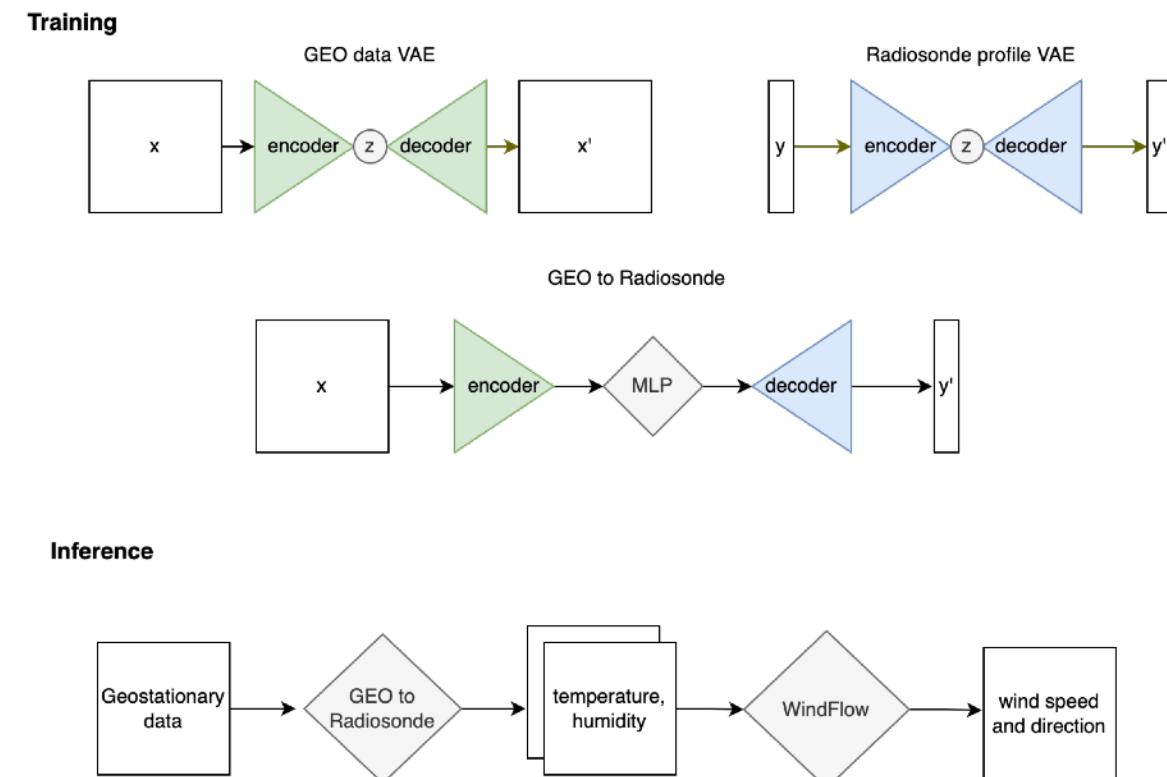

Scientific observations

1. Atmospheric profiles can be categorized into “clusters” representing different, well defined weather conditions.
2. Meteorologists can visually identify features in GEO TIR imagery for most, if not all weather conditions.

Hypothesis - A generative model can be learned to translate GEO TIR to radiosonde profiles

Approach - Learn a translation between low dimensional representations of GEO TIR and radiosondes

Variational Autoencoders (VAEs) compress high-dimensional data to a probabilistic latent representation, preserving uncertainty and extracting useful features

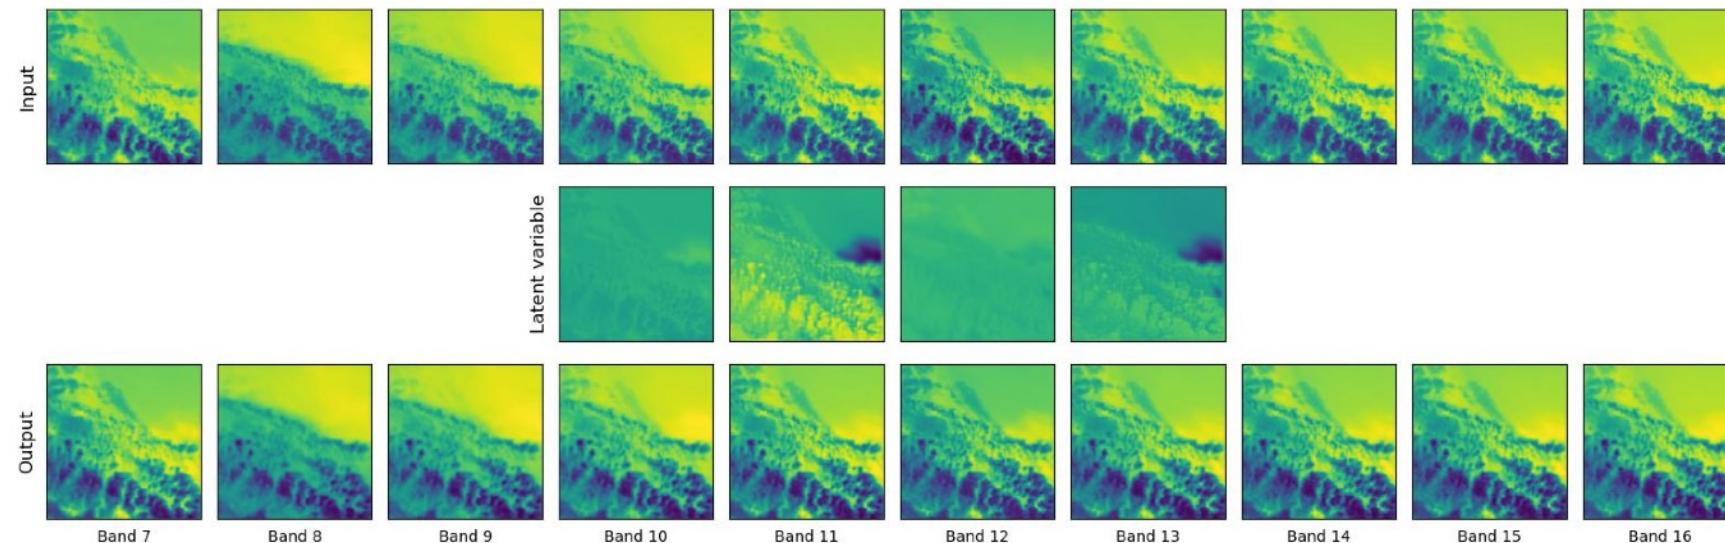

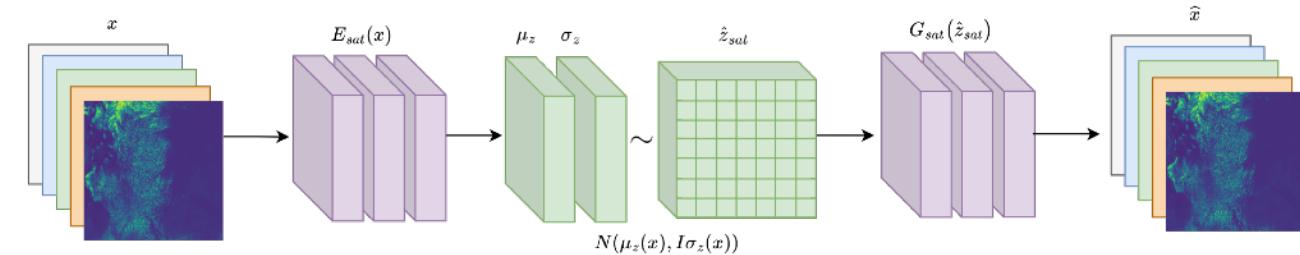

Geostationary VAE

High-fidelity VAE to learn a latent representation of GEO TIR

Compressed representation can reduce storage requirements

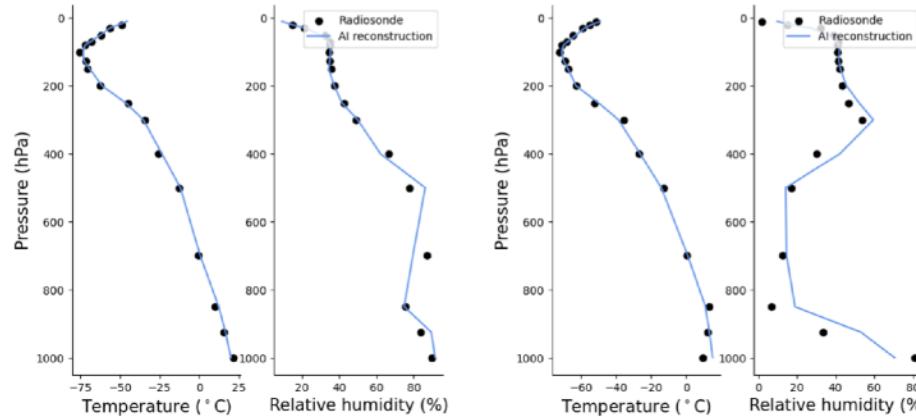

Trade-off between accuracy and compression ratio

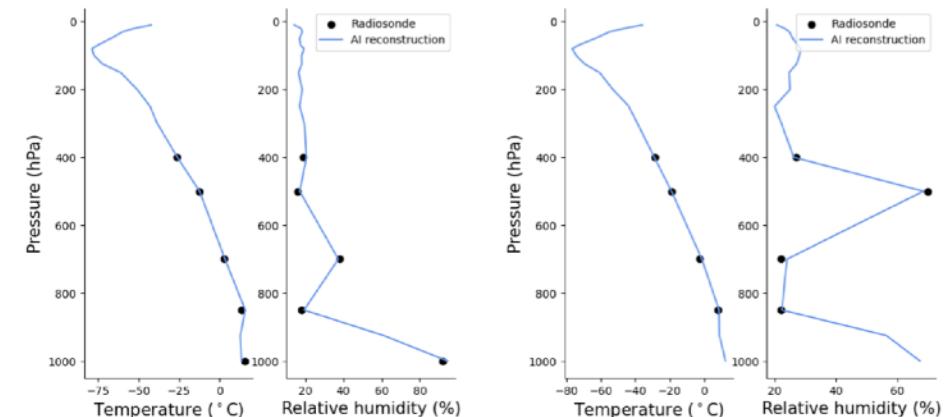

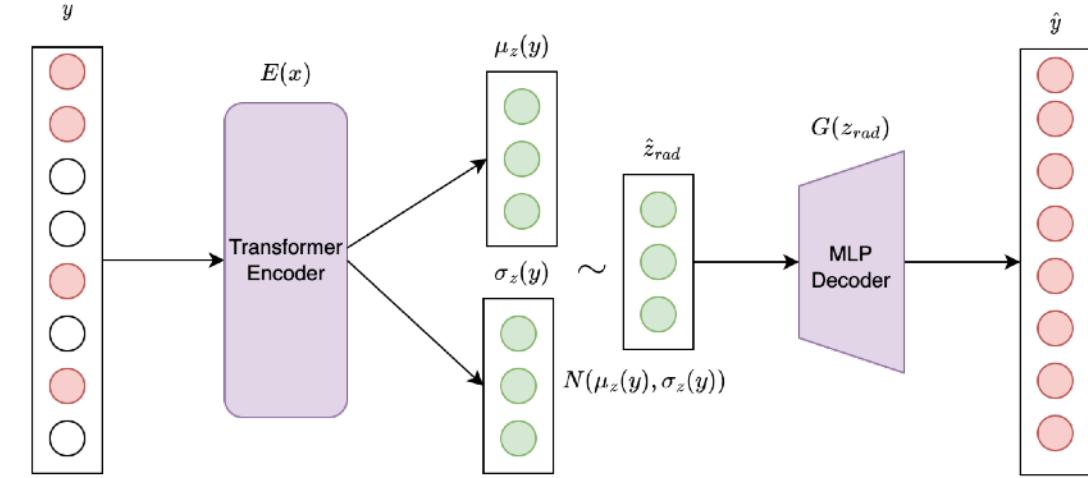

Radiosonde data reconstruction - VAE

- VAE with transformer encoder layers and MLP decoder
- Automatically fills missing values
- Uncertainty aware sampling
- Errors (dropping 20% of obs)

Temperature = 1.5° C, RH = 2.7%

Reconstructions

Gap Filled Profiles

Geostationary to 3D Profile

Predict radiosonde latent from GEO latent

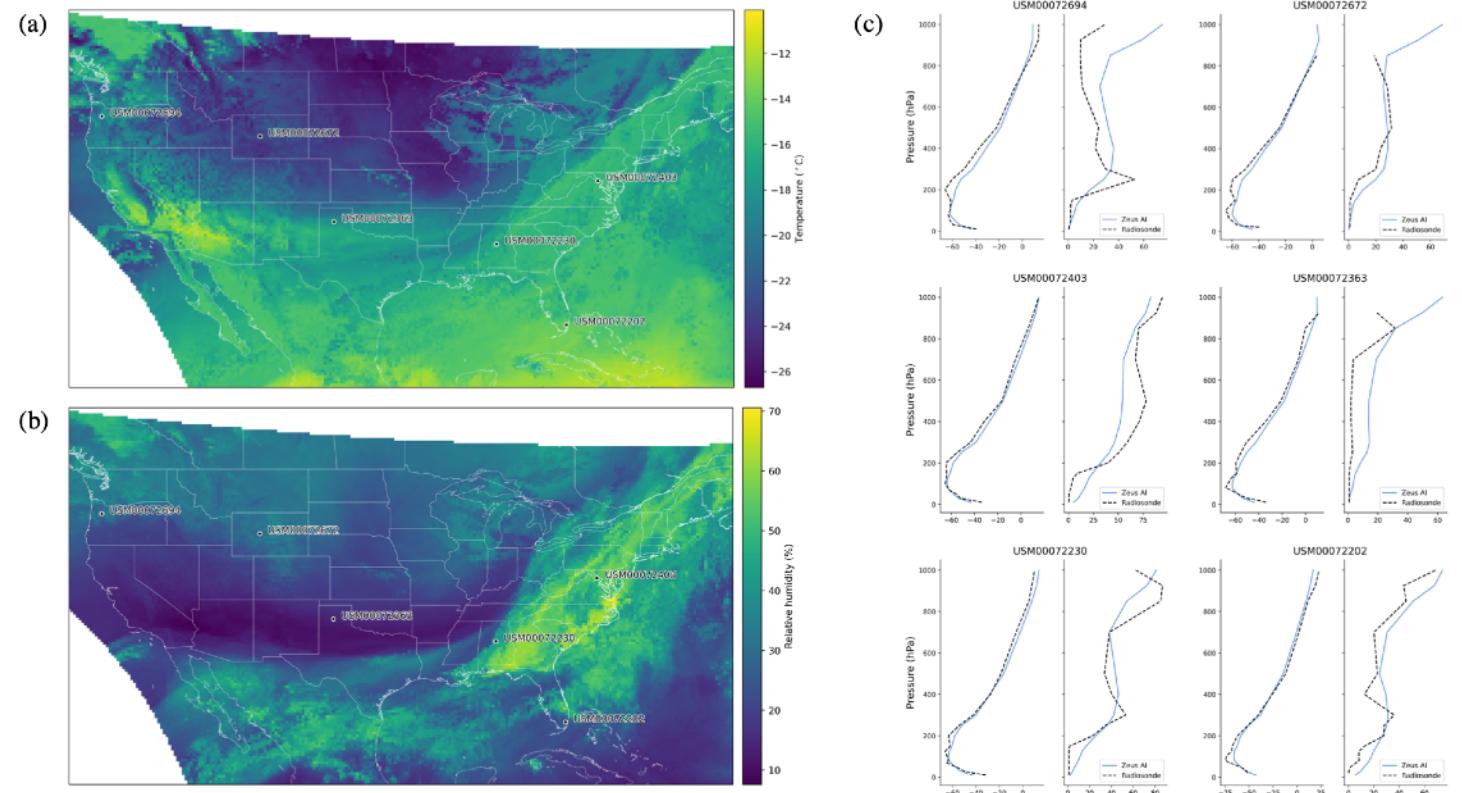

Train a model:

$$F(z_{geo}) = z_{rad}$$

such that

$$z_{geo} = E_{geo}(GEO)$$

F is defined as an MLP with 4 input features and 9 output features

500 hpa a) Temperature and b) Relative Humidity Maps

c) Vertical profiles vs Radiosonde

Preliminary Analysis: Zeus AI vs ERA5

- + Improved spatial resolution and high-res atmospheric features
- + High-refresh rate every 10-minutes
- Underestimates warm core temperature

1:1 comparisons

Test set: January-April 2021

N = 1101

Relative humidity

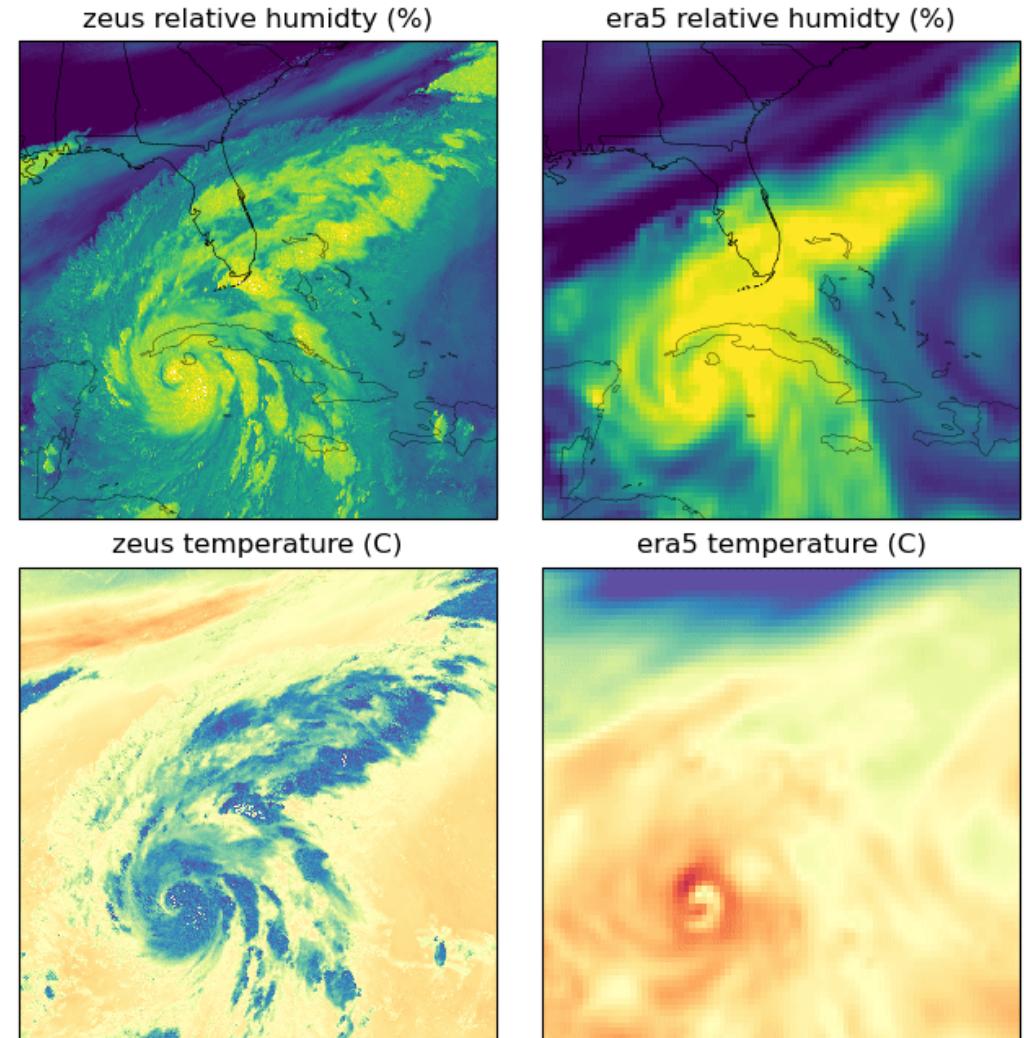

$\text{RMSE}(\text{zeus, igra}) = 15.54\%$

$\text{RMSE}(\text{era5, igra}) = 18.980\%$

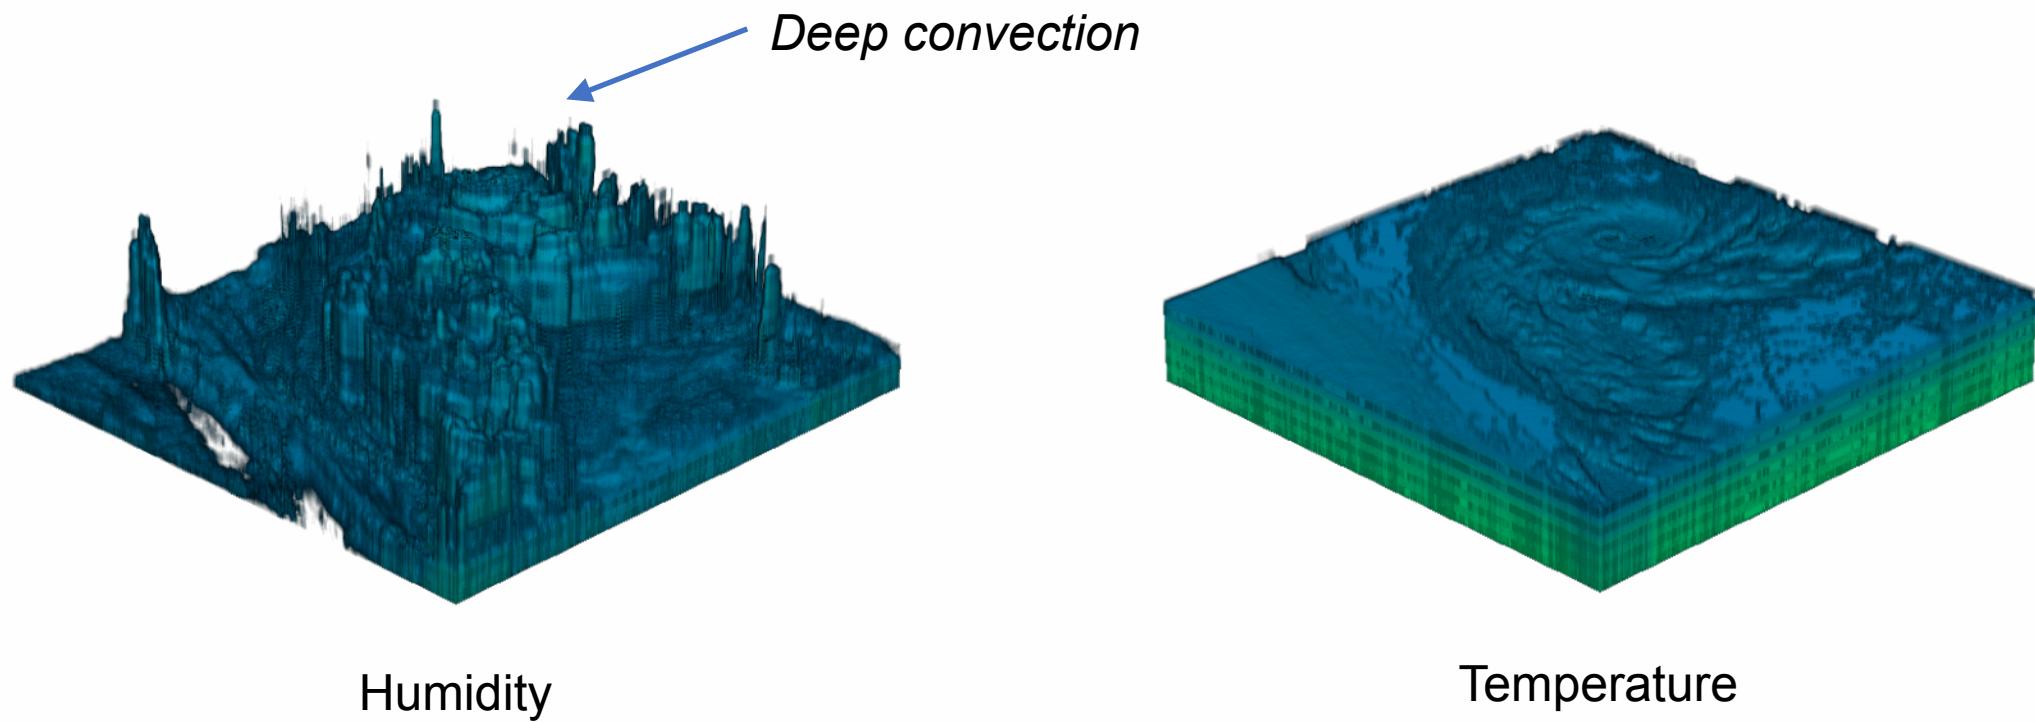

Temperature

$\text{RMSE}(\text{zeus, igra}) = 5.460 \text{ C}$

$\text{RMSE}(\text{era5, igra}) = 3.364 \text{ C}$

3D Hurricane Ian

Future Work

- Apply WindFlow to retrieved from multi-level relative humidity sequences to produce 3D winds.
- Evaluate data products using triple collocation analysis against models and observations.
- Evaluation performance for extreme events and case studies.
- Develop Neural Ordinary Difference Equations (NODEs) to effectively assimilate and smooth our 3D product.
- Apply NODE into future as a novel forecast.

Open source software

Windflow

<https://github.com/tjvandal/windflow>

Includes code for a suite of optical flow models, training, and dependencies

Windflow-light

<https://github.com/tjvandal/windflow-light>

Minimal dependencies

Efficient inference, runs on a laptop

CALIPSO cloud height prediction (In progress)

<https://github.com/tjvandal/calipso-cloud-height-prediction>

Temporal Interpolation
